 ${\it Keywords:}\ {\it fluid-structure}\ {\it interaction}\ -\ {\it blood}\ {\it flow}\ -\ {\it partitioned}\ {\it coupling}\ -\ {\it high-order}\ {\it finite}\ {\it elements}$

The present work is concerned with the partitioned solution of the multifield problem arising from a hierarchical modeling approach to cardiovascular fluid-structure interaction. Different strategies to couple the participating field solvers are investigated in detail. This includes staggered and parallel coupling algorithms as well as different methods for convergence acceleration, spatial interpolation and temporal extrapolation of coupling quantities. In the developed modeling and simulation approach, a fully resolved model of a segment of the arterial network is coupled to reduced order models in order to account for the influence of the surrounding.

There is experimental evidence that hemodynamic quantities such as the wall shear stress promote the progression cardiovascular disease. Cardiovascular FSI simulations, that can predict these quantities, are therefore of great interest and can aid in surgical planning and optimization of anastomoses shapes and graft materials.

Acknowledgements

During my work at the Institute for Ship Structural Design and Analysis at Hamburg University of Technology, from which this thesis has emerged, many great people have helped, inspired and encouraged me in one or the other way. I would like to say "thank you" here - without their input, this output would not exist.

First of all, I would like to express my gratitude to my supervisor Prof. Düster. His expertise in a broad range of topics in the field of numerical computation, calmness in explaining and enthusiasm when discussing new ideas have guided me through my first years in academia. Danke dafür! Having started at the same day in the same office, my colleague Marcel König deserves my special thanks as well. His tenacity and skills, which he was always willing to share, have contributed a lot to this thesis. Vielen Dank! Of course, I would like to thank all of my colleague at the institute for their helpfullness the many fruitful discussions. Danke!

Zooming out, I owe great thanks to my parents Christel and Ronald. They have perhaps once sparked my interest in science and support me unconditionally and without exception in everything I do. Danke für alles! I would also like to thank my friends, many of whom have inspired me technically - oftentimes without an engineering background - and all of whom have encouraged me to stay at the university after may Masters degree. Vielen Dank!

Finally, I would express my deepest thanks to my partner Johanna for her everlasting support, comprehension and love. Ich liebe Dich!

List of medical terms

abdominal	Refers to the abdomen (stomach)
adventitia	Outermost layer of an arterial wall
anastomosis	Here, connection between bypass graft and artery
aorta	The largest artery in the body
atherosclerosis	Inflammatory disease in arteries
atrium	Smaller chambers of the heart
cardiovascular	Refers to the heart and the circulatory system
coronary	Refers to the heart
diastole	Phase of the cardiac cycle, where blood enters
	in the left ventricle
distal	Away from the body center, here downstream
dorsal	Refers to the back
endothelium	Layer of cells at the lumen boundary of an artery
erythrocytes	red blood cell
femoral	Refers to the thigh region
iliac	Refers to the intestine region
intima	Innermost layer of an arterial wall
intimal hyperplasia	Abnormal thickening of the intima
leucocytes	White blood cell
media	Middle layer of an arterial wall
proximal	Towards the body center, here upstream
pulmonary	Refers to the lungs
systole	Phase of the cardiac cycle, where blood leaves
	the left ventricle
thrombocytes	Platelets activating blood clotting
thrombosis	Formation of a blood clot
ventricle	Larger chambers of the heart

Abstract

The present work is concerned with the partitioned solution of the multifield problem arising from a hierarchical modeling approach to cardiovascular fluid-structure interaction. Different strategies to couple the participating field solvers are investigated in detail. This includes staggered and parallel coupling algorithms as well as different methods for convergence acceleration, spatial interpolation and temporal extrapolation of coupling quantities as well as convergence criteria. In the developed modeling and simulation approach, a fully resolved model of a segment of the arterial network is coupled to reduced order models in order to account for the influence of the surrounding. The resulting problem is solved using five specialized field solvers, namely a fluid and a structural solver for the three-dimensional fluid-structure interaction problem, a one-dimensional blood flow solver for the surrounding vessel network, a solver for different types of windkessel models used to obtain physiological boundary conditions at the distal ends of the one- and three-dimensional models, and a solver for an elastic foundation that describes the surrounding tissue. The applicability of the solution approach is demonstrated in terms of several exemplary applications including studies of idealized and patient specific end-to-side anastomoses of bypass grafts. They are known to be prone to the development of intimal hyperplasia, i.e. a thickening of the vessel wall that may lead to occlusions in the anastomosis region. There is experimental evidence that hemodynamic quantities such as the wall shear stress promote the progression of this secondary disease. Cardiovascular FSI simulation are therefore of great interest and can aid in surgical planning and optimization of anastomoses shapes and graft materials.
